1. Logic:
    a. To check negative, we need to check the sign bit. Firstly, the EBX register is cleared, then the contents of the array is added to it. This makes sign bit 1 if it is negative number.
    b. We make jump if not signed and increment dx by 1 if it is signed (MSB is 1).
    c. We proceed to make the Most significant nibble 1. For that, first four bits are made 0, by consecutive SHL and SHR operations. Then it is XORed with 01000000 to make the first nibble as 1.
    d. Then, the result is moved to the location marked by SI, which is the newarray organized from 0400h.
2. Screenshots:
    a. [DX Register after last operation: 0004]
